Analysis Results

1. Listing Activity Duration Analysis

1. Most common listing activity categories

In Saint Petersburg, the most common category by listing activity duration is properties that remained active for more than six months.

In the Leningrad Region, the largest share of properties belongs to the category of listings active for less than three months.

This indicates that properties in the Leningrad Region tend to be removed from the market faster compared to Saint Petersburg, suggesting potentially higher sales velocity.

2. Factors influencing listing activity duration

The analysis shows that smaller apartments tend to be removed from the market faster in both regions.

Across most listing activity categories and regions, the median number of rooms is two, except for properties in the Leningrad Region with an activity duration of less than three months.

The median floor number and median number of rooms remain relatively stable across different activity duration categories.

Property size appears to be one of the key factors influencing how quickly a listing leaves the market.

3. Differences between Saint Petersburg and the Leningrad Region

The main difference between the two regions is the price level.

Saint Petersburg demonstrates an average price per square meter that is almost twice as high as in the Leningrad Region.

2. Seasonal Market Analysis

1. Monthly activity of listing publication and removal

The highest number of new property listings is observed in November.

The highest number of listings removed from the market occurs in October, which may indicate increased buyer activity during this period.

2. Relationship between listing publications and removals

The periods of high listing publication activity and listing removals generally coincide.

A positive correlation can be observed between the number of newly published listings and the number of removed listings: an increase in new listings is followed by an increase in market activity within the same or the following month.

It is also worth noting that market activity decreases during May and June compared to other months.

3. Seasonal impact on price per square meter and property area

Seasonal patterns influence both listing prices and property characteristics.

Properties are published with higher average prices per square meter during winter months, while the highest selling prices per square meter are observed during spring.

More specifically:

- The highest publication price per square meter is observed in January.
- The highest removal price per square meter occurs from January to March.

The largest properties by area are mainly published and removed from the market between February and April.

The lowest average property areas for both published and removed listings are observed toward the end of the year.

Business Recommendations

Based on the analysis, the most profitable strategy for maximizing revenue is to publish higher-priced properties at the beginning of the year, when market conditions are more favorable.

Properties with larger areas also demonstrate stronger market potential during the first months of the year.

By the end of the year, smaller properties with lower price per square meter may have better market performance.

These seasonal insights can help real estate agencies optimize marketing campaigns, determine the best listing periods, and develop region-specific sales strategies.
